Abstract

This paper analysis and compares the volatility of seven cryptocurrencies – Bitcoin, Dogecoin, Ethereum, BitcoinCash, Ripple, Stellar and Litecoin – to the volatility of seven centralized currencies – Yuan, Yen, Canadian Dollar, Brazilian Real, Swiss Franc, Euro and British Pound. We estimate GARCH models to analyze their volatility. The results point to a considerably high volatility of cryptocurrencies when compared to that of centralized currencies. Therefore, we conclude that cryptocurrencies still fall far short of fulfilling all the requirements to be considered as a currency, specifically regarding the functions of store of value and unit of account.

JEL Classification: E51, G12, G15; G17, G23.

Keywords: Centralized currencies, cryptocurrencies; GARCH models; volatility.

A revised version of this paper has been published in Duarte, A. P., Sol Murta, F., Baetas da Silva, N., Vieira, B.R. (2023). Flip the Coin: Heads, Tails or Cryptocurrencies? *Scientific Annals of Economics and Business*, 70(SI), 1-18. https://doi.org/10.47743/saeb-2023-0013

This work has been funded by national funds through FCT – Fundação para a Ciência e a Tecnologia, I.P., Project UIDB/05037/2020

1. Introduction

Cryptocurrencies – especially the most famous one, the Bitcoin – are very popular and are a controversial topic in the economic literature nowadays (e.g., Kristoufek, 2013; Yermack, 2013; Baur et al., 2018; Aalborg et al. 2019; Cagli, 2019; Makarov and Schoar, 2020). Cryptocurrencies use to buy goods and services is increasing and they are becoming an important medium of exchange. However, they are far from assuming all the functions inherent to the centralized currencies, especially the unit of account and store of value. The main reasons for that are their high level of price volatility and their speculative nature (Cheah and Fry, 2015; Dyhrberg 2016; Blau, 2017; Katsiampa, 2019a; Tiwari et al., 2020), as well as the fact that the cryptocurrencies are associated with illegal activities (Aldridge, 2017; Durrant, 2018; Cuervo et al., 2019; Swammy et al., 2019; Choi et al., 2020).

Since the creation of Bitcoin in 2008 (Nakamoto, 2008), cryptocurrencies are seen as an alternative investment, especially in periods of crisis, which can indicate that they may assume the function of store of value or even unit of account. However, the excessive price volatility is a problem and without its elimination, the fulfillment of these functions will be impossible.

This paper analyzes the volatility of seven cryptocurrencies (Bitcoin, Dogecoin, Ethereum, BitcoinCash, Ripple, Stellar and Litecoin), compared to the volatility of seven centralized currencies from different economic backgrounds (Yuan, Yen, Canadian Dollar, Brazilian Real, Swiss Franc, Euro, and Pound Sterling).

Regarding the methodology, we estimate Generalized AutoRegressive Conditional Heteroskedasticity (GARCH) models. Our results point to the existence of strong volatility cryptocurrencies' returns, in line with other papers (Yermack, 2014; Balcilar et al., 2017; Yi et al., 2018; Bouri et al., 2019; Katsiampa et al., 2019; Katsiampa, 2019b; Kumar and Anandarao, 2019). The volatility of cryptocurrencies is significantly higher than the volatility of currencies. For that reason, cryptocurrencies will have a hard time being considered a measure of value and a standard of value. For now, they can only fulfill the function of means of payment. This paper gives an additional value to the economic literature because it compares several cryptocurrencies against various currencies from different economic and geographic areas with distinct dynamics. To best of our knowledge this is the first time that the volatility of cryptocurrencies and currencies

is compared. Therefore, we contribute empirically to the debate around the role of the cryptocurrencies, in the line of Eichengreen (2019).

The paper has five sections. Section 2 presents a brief literature review. Section 3 is dedicated to describing the data and the methodology. Section 4 presents and discusses the main results. Finally, section 5 draws the conclusions.

2. Literature review

We live in a world of fiat money since the development of societies led to an evolution of the concept of money, the most recent being digital money. Commodity money was the first concept in the primitive economies. Later, representative currency appeared. Nowadays, we have fiat money, which is legal and is issued and controlled by central banks – the euro, for example, issued by the European Central Bank (ECB). Fiat money exists in physical forms (banknotes and coins), and bank deposits (a computer record). There are even countries in Europe (e.g., Netherlands and Sweden) where electronic payments are superior to cash payments because they are more convenient, safer, and cheaper. Recently, cryptocurrencies appeared, the most famous being the Bitcoin. They are not supervised by any regular entity or central bank (for surveys, see Spahn, 2001; Helleiner, 2002; McLeay et al., 2014, and Eichengreen, 2019).

Jevons (1896) defined three functions that an asset must satisfy in order to be considered money. First, it must be means of payment. This function allows for saving time and reducing transaction costs. Another function is unit of account (it makes possible to compare prices of goods and services, as well as assign them a value). Last but not least, money need to be store of value over time. Economic agents should be able to use a currency for investments, as well as preserve their purchase power.

Despite these three functions that an asset must satisfy to be considered a currency, Hazlett and Luther (2020), are convinced that what matters is whether the asset is accepted by the economic agents. On this point, the world of cryptocurrencies, with an ascending acceptance and use, seems to be gaining ground in replacing currencies soon. Nevertheless, at best, cryptocurrencies are only an imperfect substitute for currencies.

The first cryptocurrency considered successful, with the highest capitalization index and the most users on social media and online exchange offices, was Bitcoin, created by Satoshi Nakamoto in 2008 (Nakamoto, 2008). This cryptocurrency resolves a potential problem associated with digital currencies, the double-spending problem. It

consists of the lack of a mechanism that prevents the user from using the digital currency for more than one payment (Bação et al., 2018). Bitcoin is a peer-to-peer mechanism and because of its algorithm and the cryptography used in Blockchain, this problem does not exist. This cryptocurrency is traded without the intermediation and supervision of any monetary authority. The transactions are verified by each user and, at the same time, are recorded on Blockchain, which is publicly available (Duarte et al., 2018). Each transaction creates a new block that is connected to the previous transaction. In each block a new code that identifies the transaction is created, called hash, which is also connected to the previous code, called previous hash.

Compared to other cryptocurrencies, Bitcoin has a particularity, its offer is limited to 21 million units. Nowadays, 18 million Bitcoins are in circulation. While the Central Banks have the monopoly of creating money and can control their offer with monetary policies, this does not happen in the cryptocurrency world. This eliminates the possibility of inflationary processes. On the contrary, deflation is more likely.

Despite this advantage, the lack of monetary policy drives the cryptocurrencies out of the realm of currencies. Yermack (2013) highlights the high volatility of Bitcoin and cryptocurrency in general, which can jeopardize the possibility of their being affirmed as a currency. Other authors (Fink and Johann, 2014, Cheah and Fry, 2015; Dyhrberg 2016; Blau, 2017; Katsiampa, 2019a and Tiwari et al., 2020) empirically confirm this reality, as well as its speculative nature, which does not contribute to the possibility of cryptocurrencies fulfilling the functions of measure and standard of value.

Regarding the measure of value, Wallance (2011) mentions the episode of the first purchase of goods through Bitcoin on the 21st of May 2010. Two pizzas were bought for 10,000 Bitcoins which equaled 25 dollars at the time. Today, at the current price of Bitcoin, this purchase would represent more than 500 million dollars. Therefore, cryptocurrencies will have a hard time functioning as a measure of value and standard of value, due to their price instability.

Recently, Hazlett and Luther (2020) point out that since Bitcoin is frequently used as a medium of exchange that can be enough to consider it a currency. Some countries have already accepted Bitcoin (e.g., El Salvador) as a medium of exchange.

The increase in the use of cryptocurrencies as a medium of exchange, with the lack of financial regulation, results in associating their use with criminal activities, such

as money laundering, drug or gun trafficking¹. Cryptocurrencies payments are similar to Cash payments. They use a decentralized system without visible intermediates and allow anonymous transactions, and for that reason, they are often related to illegal activities (Durrant, 2018; Cuervo et al., 2019; Swammy et al, 2019; Choi et al., 2020; Hendrickson and Luther, 2021).

However, as Steinmetz et al (2021) mentions, this association is made by those who know little about cryptocurrencies. The fact that every transaction is recorded in the Blockchain discourages or even prevents the use of cryptocurrencies for illicit activities since it is possible to know who is involved. According to Pacheco (2018), only 1% of all transactions of Bitcoin relate to illegal activities. However, about 3 to 5% of the fiat money economy results from illicit activities.

The impact that cryptocurrencies have been having on the global economy is high. Nowadays there are more than 6,500 cryptocurrencies in circulation, according to CoinMarketCap². Most central banks have warned about the increase in using cryptocurrencies and their legality, in particular, for the possibility of using them for corruption. Gonzálvez-Gallego and Pérez-Cárceles (2021) believe that using cryptocurrencies should be promoted and not dismissed as long as there are policies that control their use. However, that is a bit ironic: if policies existed, it would no longer be a decentralized system. The authors also mention that the governments need to promote stable financial institutions, because that alone would prevent people from choosing cryptocurrencies instead of currencies. We must keep in mind that the cryptocurrency phenomenon began due to the instability caused by the financial crisis of 2008.

Another option is the creation of centralized cryptocurrencies (e.g., Auer et al., 2021 and BIS, 2021). This hypothesis is being considered by many central banks, such as the ECB, the Bank of England, and the Central Bank of Sweden, which propose their own digital coins, the Central Bank Digital Currencies (CBDC). The U.S. Federal Reserve is still considering how CBDC may fit into the U.S. money and payments landscape (Board of the Federal Reserve System, 2022).

5

¹ The recent war in Ukraine has drawn even more attention to the use of cryptocurrencies in this context. One of the most famous historical cases is the Silk Road, a dark-web market that allowed transactions of drugs (DeVries, 2016). Another one is Mt. Gox, a Bitcoin exchange based in Tokyo that was hacked and exposed the records of 18 million transactions (Gandal et al., 2018).

² https://coinmarketcap.com/.

The Central Bank of Sweden, Riksbank, although the oldest in Europe, is the first one in the race to create a CBDC, the eKrona. This project is still in a pilot phase, studying what effects this digital currency would have on the economy and Sweden's laws, as well as what the best model would be for its creation (Sveriges Riksbank, 2021). The goal is that eKrona could work as a complement to physical money and have a system of use accessible to the entire population. It should be noted (Duarte, 2022) that the launch of this project was driven by the increasing dematerialization of money in Sweden, a fact that the central bank believes could result in situations of marginalization, with a user wanting to pay in physical money and the seller no longer accepting it.

Like Sweden's case, China is also in the race to develop a digital currency. According to the BBC³, cryptocurrency transactions are forbidden in this country since 2019. Still, according to Forbes⁴, China intends to create its own digital currency that is supervised and centralized, going against the initial concept of what a cryptocurrency is (e.g., Goodell et al., 2021 and Lee et al., 2021).

Despite the announcement of these pilot projects, the Bahamas was the first country to effectively launch a global CBDC, called the "Sand dollar", in October 2020. In February 2021, the United Arab Emirates joined China, Hong Kong, and Thailand in a joint cross-border CBDC to test the use of Distributed Ledger Technology (DLT) for foreign currency payments.

The UK, Japan and the ECB are also considering their entry into digital currencies. The digitization of central bank currencies is in fact a global rapidly growing process, particularly in the euro area. It is expected that the launch of a digital euro will revolutionize the lives of all European economic agents through the changes it will introduce in their lives, and in the way, payments are made in the future (Duarte, 2022).

The digital euro project was announced by the ECB in July 2021, right in the middle of the Covid-19 pandemic. This does not mean, however, that the ECB will necessarily issue a digital euro immediately, but rather that it will get ready to possibly issue it in the near future, considering any changes in the European legislation that may have to be made. As mentioned by the ECB⁵, a digital euro will guarantee that agents in the euro area can maintain cost-free access to a simple, universally accepted, safe and

⁵ https://www.ecb.europa.eu/paym/digital_euro/html/index.en.html.

trusted means of payment. The digital euro will still be a euro, like banknotes and coins, but digital, turning the euro area into a global digital player. It will be an electronic form of money issued by the ECB and national central banks and accessible to all economic agents. A digital euro will not replace cash, but rather complement it. The Eurosystem will continue to ensure that European citizens would have access to cash across the euro area, giving them an additional option for making payments, thus contributing to greater accessibility and inclusion in the European financial space. Using a digital euro, agents could have the same level of confidence as with bank currencies, since they would be both backed by the monetary authority. A digital euro would consequently become a digital symbol of progress and integration in Europe⁶.

3. Data and methodology

This paper analyzes the volatility of seven cryptocurrencies (Bitcoin, Dogecoin, Ethereum, BitcoinCash, Ripple, Stellar and Litecoin), compared to the volatility associated with money, specifically Yuan (CNY), Yen (JPY), Canadian Dollar (CAD), Brazilian Real (BRL), Swiss Franc (CHF), Euro (EUR) and Pound Sterling (GBP). These currencies belong to different monetary and geographic areas, thereby allowing a more robust analysis. The data consists of the daily prices of both, cryptocurrencies, and currencies.

The cryptocurrency data was collected from the Coindesk site (https://www.coindesk.com/, accessed November 6, 2021), and refers to the closing prices in American dollars (USD). For each currency, we considered the daily exchange rates in USD. This data was collected from the Federal Reserve Bank of Saint Louis (https://www.stlouisfed.org/, accessed November 6, 2021).

For each variable, we tried to collect the greatest number of observations possible. Table 1 shows the data available (initial observation and final) for the seven cryptocurrencies.

-

⁶ For more details see Duarte (2022).

Table 1: Cryptocurrencies (initial observation and final observation)

Criptocurrency	Initial Observation	Final Observation		
Bitcoin (BTC)	03/11/2014	05/11/2021		
Dogecoin (DOGE)	27/02/2019	05/11/2021		
Ethereum (ETH)	16/12/2016	05/11/2021		
BitcoinCash (BCH)	01/02/2018	05/11/2021		
Ripple (XRP)	01/06/2018	05/11/2021		
Stellar (XLM)	01/12/2018	05/11/2021		
Litecoin (LTC)	01/02/2018	05/11/2021		

Source: Authors, using the CoinDesk database (https://www.coindesk.com/, accessed November 6, 2021).

The cryptocurrency with the lowest number of observations is Dogecoin (DOGE), with an initial observation only on 27/02/2019. For that reason, in this study the period of analysis starts in that date, in order to have a fair and comparative analysis. The period of the analysis extends from 27/02/2019 to 05/11/2021, which gives us a significant number of observations, since we are working with high-frequency data. It is important to note that the cryptocurrency market functions daily, while the currency market is only available on workdays. Figures 1 and 2 illustrate the evolution of the daily prices of cryptocurrencies and exchange rates in USD, respectively.

Looking at Figure 1, we observe a general growth in the prices of cryptocurrencies since the beginning of 2021. After May 2021, there was a significant increase in almost every cryptocurrency. Bitcoin (BTC) clearly has the highest prices compared to the other cryptocurrencies, presenting its highest value on October 26, 2021, when one BTC was worth 63.081,80 dollars. In contrast, we have Dogecoin (DOGE), with the lowest prices. The highest price was reached on May 8, 2021, with a value of 0.72 dollars per unit.

As for the seven currencies (Figure 2), they do not present significant changes in their exchange rate. Still, some currencies, for example, the Brazilian Real (BRL) show a high depreciation, since January 2020. In contrast, we have the Yuan (CNY), which, since May 2020, has shown a significant trend of appreciation. In both cases, the relative volatility of these currencies is low, which naturally gives them an advantage compared to cryptocurrencies in being considered a measure of value and a standard of value.

BTC/USD DOGE/USD BCH/USD ETH/USD XRP/USD XLM/USD LTC/USD

Figure 1: Cryptocurrency daily prices in USD

Source: Authors, using the CoinDesk database (https://www.coindesk.com/, accessed November 6, 2021).

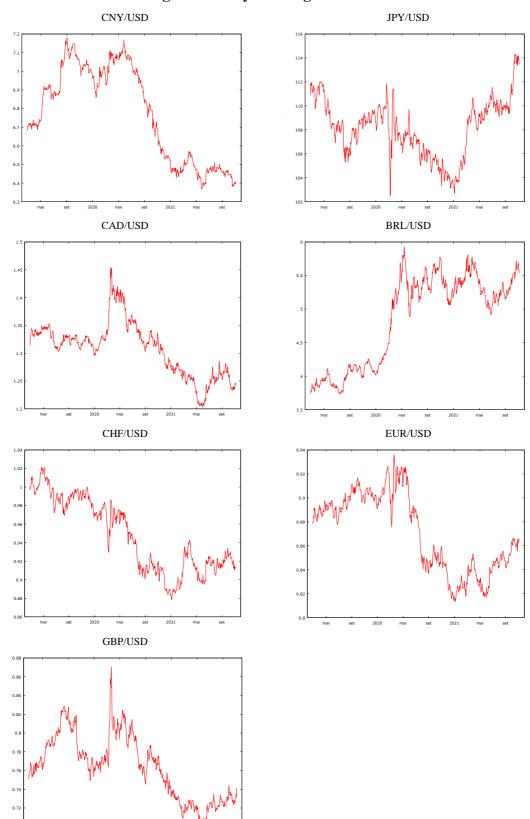

Figure 2: Daily exchange rates in USD

Source: Authors, using data from the Federal Reserve Bank of Saint Louis (https://www.stlouisfed.org/, accessed November 6, 2021).

Since the main focus of this paper is to analyze the volatility of the cryptocurrencies and comparing it with the volatility of the chosen currencies, following e.g., Bouri et al. (2019), Kumar and Anandarao (2019), and Katsiampa (2019b), we started by computing the first difference of the logarithm, the return.

The econometric model that is used to study the volatility of the series of our study is the Generalized AutoRegressive Conditional Heteroskedasticity (GARCH), developed by Robert Engle (Engle, 1982; Bollerslev, 1986). The ARCH/GARCH models are frequently used to model financial time series that show clusters of volatility over time. There are periods with high instability alternating with stable periods.

The estimated models (using the program GRETL) follow the formulation:

$$Y_t = a_0 + \varepsilon_t \tag{1}$$

where Y_t represents each series of volume and return and ε_t follows a process of type:

$$\varepsilon_t = z_t \sigma_t \tag{2}$$

with $z_t \sim i.i.d.$ (0,1) and σ_t follows a process of type GARCH(p,q):

$$\sigma_t^2 = \omega + \sum_{i=1}^q \alpha_i \, \varepsilon_{t-i}^2 + \sum_{i=1}^p \beta_i \sigma_{t-i}^2$$
 (3)

where $\omega \geq 0$, $\alpha_i \geq 0$ e $\beta_i \geq 0$.

The selection of the GARCH model aims to determine the autoregressive component (p) and the coefficient of the error terms (q). Next, we present the results of the estimation of GARCH models for the series of both cryptocurrencies and currencies.

4. Money and cryptocurrencies: A volatility analysis

We will analyze the descriptive statistics, the stationarity, and the volatility of the returns of cryptocurrencies and currencies. Figures 3 and 4 show the behavior of the returns of cryptocurrencies and the seven currencies in USD, respectively. The figures presented suggest the existence of periods with high and persistent volatility, alternating with periods with low volatility. In the case of cryptocurrencies, there are clearly peaks that can translate into phases of high instability.

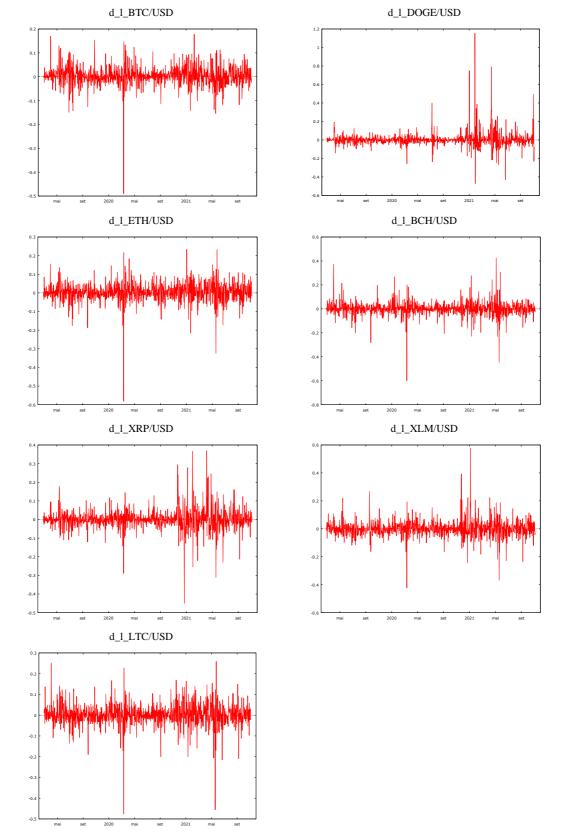

Figure 3: Cryptocurrency daily returns in USD

Notes: "d" identifies the first difference of the series. "l" is the logarithm of the variable. **Source:** Authors, using the CoinDesk database (https://www.coindesk.com/, accessed November 6, 2021).

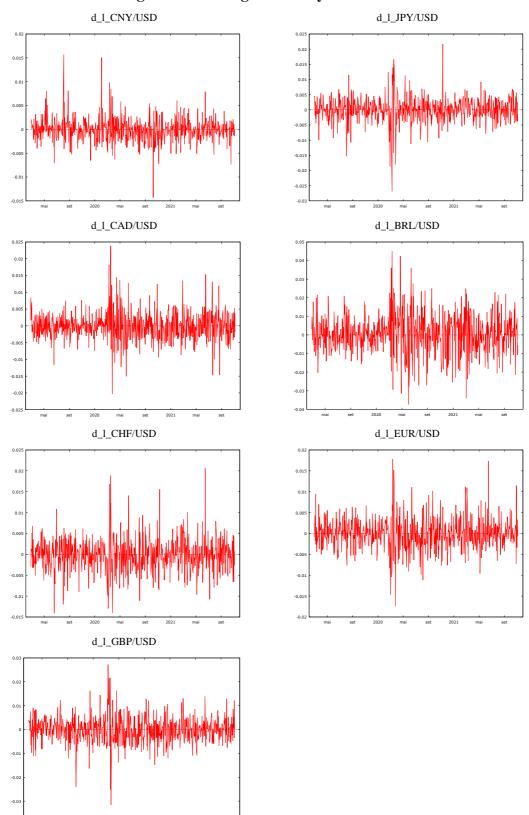

Figure 4: Exchange rate daily returns in USD

Source: Authors, using the CoinDesk database (https://www.coindesk.com/, accessed November 6, 2021).

Analyzing the descriptive statistics of the logarithmic rates of change of the cryptocurrencies (Table 2), DOGE presents the highest average return, followed by ETH and BTC. This result was not expected. Due to the popularity of the BTC, it was expected that among the seven cryptocurrencies, it would present the highest average return, which does not happen. This may be explained by the low variation in prices of BTC compared to the other cryptocurrencies. Nevertheless, BTC presents an average return twice as high as XRP and XLM, which is something to keep in mind when looking at cryptocurrencies

⁷ ADF and KPSS tests statistics were also computed for the prices and the exchange rates. The results show that the series are non-stationary for all the cases. Results can be provided upon request.

as speculative investments. BitcoinCash (BCH) and Litecoin (LTC) are the cryptocurrencies with the lowest average return, presenting almost the same results.

Source: Authors, using data from the Federal Reserve Bank of Saint Louis (https://www.stlouisfed.org/, accessed November 6, 2021).

Focusing on the standard deviation, it points out the high level of volatility of the returns (Table 2) connected to cryptocurrencies, with particular emphasis on the volatility of DOGE, BCH e XLM. Bitcoin is the cryptocurrency with the lowest level of volatility.

On the other hand, analyzing the descriptive statistics of the logarithmic rates of change in the exchange rates (Table 3), we can see with some surprise that the highest medium return belongs to BRL. This result can be explained by the high volatility of this currency during the period in analysis, which is still significantly lower when compared to the volatility of the other seven cryptocurrencies mentioned earlier. In contrast, the Swiss franc (CHF), the Canadian dollar (CAD), and the yuan (CNY) have the lowest

medium returns, even presenting negative values. CNY, EUR, CFH, and JPY have the most stable behavior (the lowest standard deviations), which was expected, since they have such an important role as international reserve currencies. Curiously, of the seven currencies that were studied and belonged to different monetary and geographic areas, the Pound Sterling (GBP), after BRL, is the one that shows the highest volatility. We can interpret this result by the loss of importance of the Britain currency as a unit of account and international store of value, due to the BREXIT.

Comparing Tables 2 and 3, we observe that the mean of returns of all currencies is significantly lower than the mean of returns of cryptocurrencies. We can also clearly see the high discrepancy of their standard deviation values, with cryptocurrencies presenting much higher volatility than currencies. Even the highest standard deviation value of currencies (1.0307 of BRL) is significantly lower than the lowest standard deviation value of cryptocurrencies (4.1432 of BTC). This result empirically confirms the difficulty that cryptocurrencies will have in assuming the functions of unit of account and store of value in the near future.

For the analysis of the stationary characteristics of the series, we ran two tests, a test of unit root, the Augmented Dickey-Fuller (Dickey e Fuller, 1979) - ADF - and a stationary one, Kwiatkowski-Phillips-Schmidt-Shin (Kwiatkowski et al., 1992) - KPSS. As we can see, every series are I(0). We can proceed with the study of volatility.

The methodology used to study the volatility of the cryptocurrency returns and exchange rates was the GARCH model. The LM test does not reject the null hypothesis of ARCH effects on Bitcoin and Yuan (see again Table 2 and 3). In this case, we expect that the optimum model only has variance lags. For the remaining cases, it will be a GARCH model. In the process of choosing the best model, the information criteria of Schwarz-BIC (Schwarz, 1978) were used, as we can see in Table 4.

The numbers in bold in Table 4 identify the chosen model. After selecting the most appropriate GARCH model for each series, we analyzed the unconditional variance of each model. Tables 5 and 6 present the results of the estimates of the selected models for the cryptocurrencies and the exchange rates, respectively.

The unconditional variance points out the volatility of each series or its variance in the long term. The results show that the return of cryptocurrencies it is more volatile when compared to the exchange rate return. In particular, Dogecoin (DOGE) is the cryptocurrency that presents the highest value, while Bitcoin (BTC) has the lowest. Focusing on the exchange rate, Yuan (CNY) presents the lowest volatility and the Brazilian Real (BRL) the highest. Even though the Brazilian Real has the highest volatility, the volatility of cryptocurrencies is substantially higher, confirming the idea that they cannot replace the currencies.

The results are in line with some papers on the same topic (Yermack, 2014; Balcilar et al., 2017; Yi et al., 2018; Bouri et al., 2019; Katsiampa et al., 2019; Katsiampa, 2019b; Kumar and Anandarao, 2019) that used similar methodologies.

Regarding the volatility of the cryptocurrencies, we can state that, although we are in the presence of an admirable world of cryptocurrencies, the volatility of their returns is very high. The cryptocurrencies will have a hard time replacing the currencies, if they ever do.

5. Conclusion

This paper aimed to study the volatility of seven main cryptocurrencies (Bitcoin, Dogecoin, Ethereum, BitcoinCash, Ripple, Stellar and Litecoin) that are traded in exchange offices and compare it to the volatility of seven currencies (Yuan, Yen,

Canadian Dollar, Brazilian Real, Swiss Franc, Euro, and Pound Sterling) that belong to different and distinct monetary areas.

This study tried to find and analyze similarities and differences between the world of cryptocurrencies and currencies. We started by analyzing the behavior of the cryptocurrencies and the exchange rates. After, we investigated the stationary characteristics of their returns. Finally, we used GARCH models to examine the levels of volatility of both returns and compared it.

The results suggest that the mean of returns of all currencies is significantly lower than the mean of returns of cryptocurrencies. Also, the volatility of the returns of cryptocurrencies is considerably higher when compared to the currencies. Among the seven cryptocurrencies that were studied, DOGE (Dogecoin) presented the highest, followed by Ripple (XRP). Surprisingly, Bitcoin is the cryptocurrency with the lowest volatility. Still, when compared with the volatility of any exchange rates, the volatility of the most famous cryptocurrency is considerably higher.

In this context, we conclude that cryptocurrencies are far from checking all the boxes to be considered a currency, especially the unit of account and the store of value functions. By a stretch of good will, cryptocurrencies can be seen as an imperfect substitute for currencies. Even so, we do not discard the possibility of them being accepted as currencies in the future. But, right now, the currencies are by far safer and more stable, while the cryptocurrencies are, for the most part, seen and sought after as speculative assets.
